SportsEngine API Integration

This section defines the integration of the SportsEngine API into the project to pull member data. The more explicit use of the SportsEngine API will be to:

- Pull member data
- Cache member records locally in a database
- Cached data will be used to:
    - Control which users are allowed to access the system
    - Perform basic eligibility checks for club administrators
    - Replace user-based dropdowns and selection lists throughout the application (clubs, contacts, members, etc.)

The data that is currently gathered per member record is:

- club_code
- persona_id
- membership_number
- first_name
- last_name
- membership_name
- eligibility_status
- email
- _key (“persona:” + persona_id)

The API uses GraphQL as its query language. The use of the SportsEngine API is documented on their website: SportsEngine API

For our purposes we will mainly just use a readme (in the API directory) or good comments in the code that makes the api calls to document for future developers.

For integration into the project, there will be a script that pulls as much user data as possible every 60 seconds (sportsEngine limit). This script will run until everything is up to date. Then Scott plans on using a cron job to run this script at certain times.

V3

This section focuses on the completion of “version 3” which has already started development and plans to completely overhaul the user interface for administrators (for context if “users” are mentioned later, we are talking about admins).

It is less of an addition, and more of a re-write. This new system has its own database, and is separated into its own section and components, and has very. This system uses the metronic template for styling and css. So far the system includes:

Login.php:

This script displays the login screen, and will check form input and hand off to login_verify.

Login_verify.php:

This script handles the user input to ensure that the login is valid.

Functions.php:

List of functions used across all the scripts.

Layout.php:

Handles the css and styling using metronic, all other scripts will include this script.

Dashboard.php

Will display a dashboard page, where users can then navigate to any of the other pages in the system.

Sanctions.php:

This will display a list of sanctions where admins can create, edit, approve, or deny sanctions. File uploads for certificates of insurance is a planned feature as well.

Incidents.php:

This script will display a list of incidents for admins to observe, allowing them to create, or edit incidents. There should be functionality for uploading relevant documents to the incident.

Clubs.php

This will display a list of clubs where admins can create and edit clubs.

Users.php

This will display a list of users where admins can create and edit users.

Sites.php

This will display a list of sites and buildings where admins can create and edit sites, which will have their own set of buildings which can be created and edited.

TIC.php

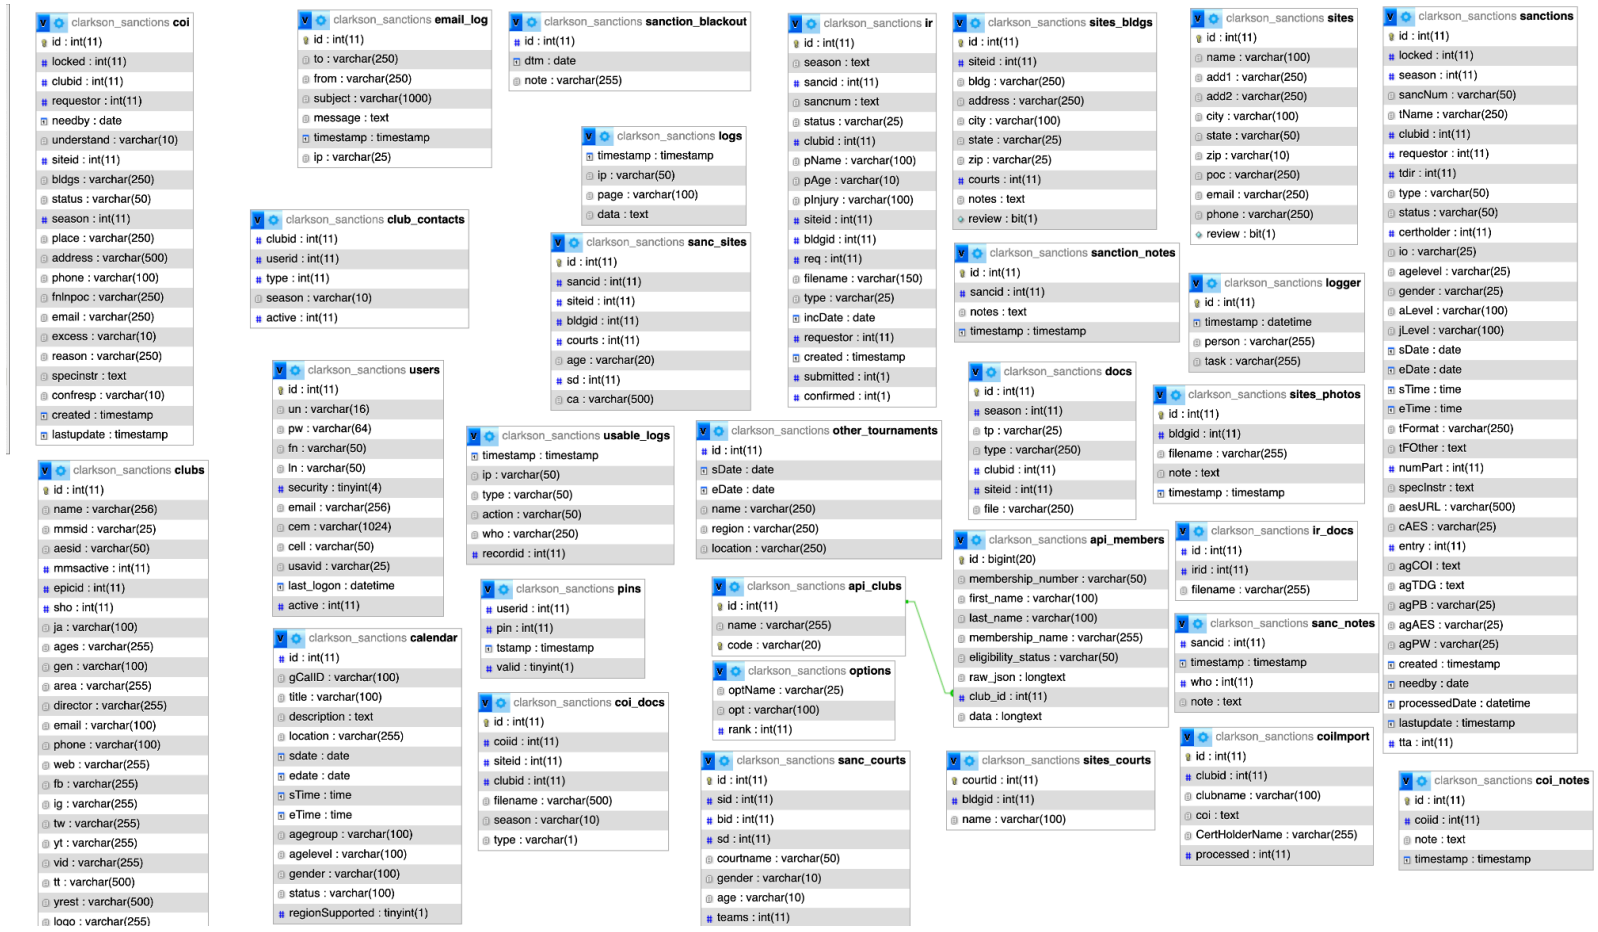
This has not been implemented yet, but is planned to handle tickets of insurance. Which is an integral function of the system.

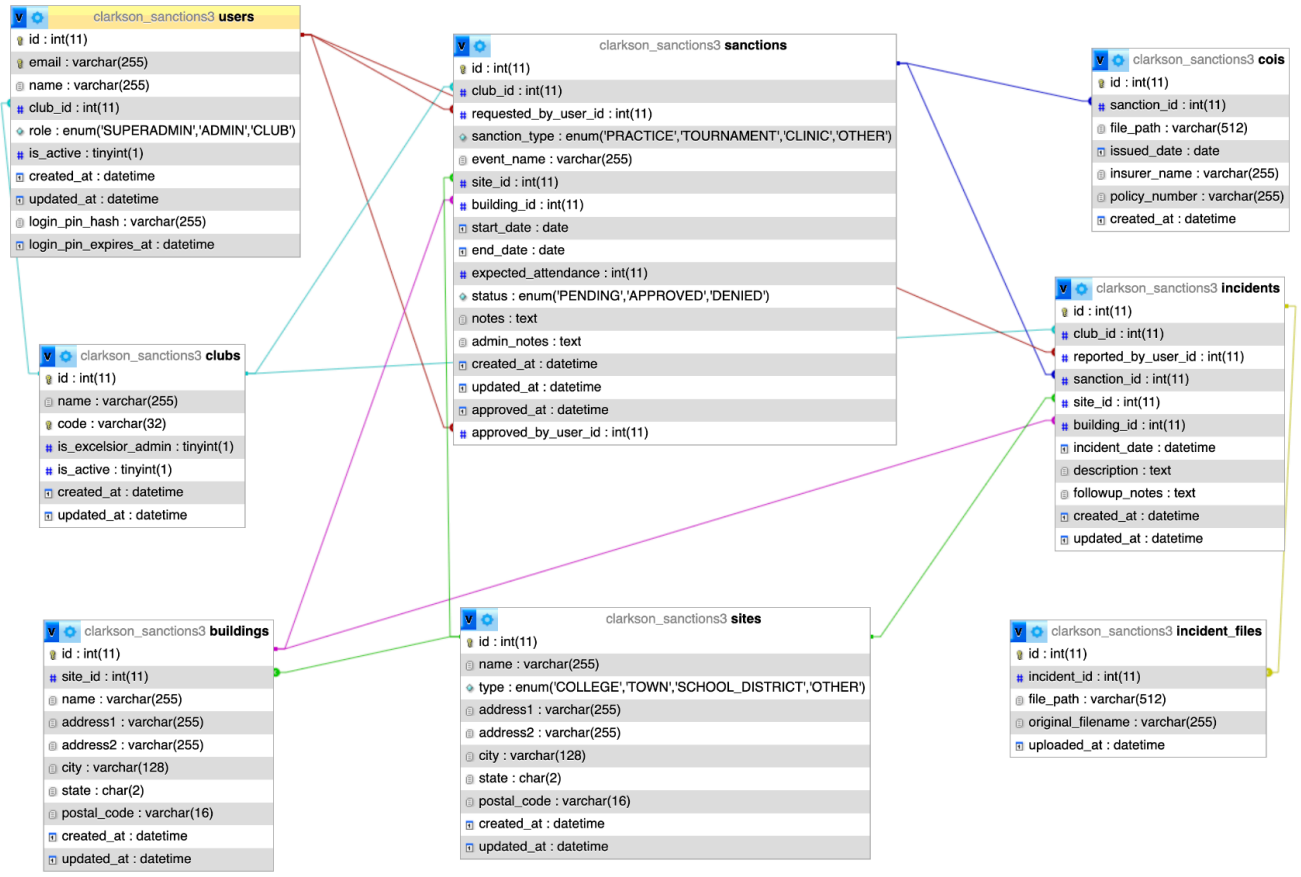
Step through of the current and new administrator user interface:

https://scribehow.com/viewer/Add_and_Manage_Sanctions_Incidents_Sites_and_Club_Information__J58DcHuyRFqStYDF0F5d3w
(step 64+ show v3, but keep in mind it is very out of date compared to the current version)

Current Database Schema

Here is the relational schema of the current database, as we can see it is kind of a mess and also barely has any relationships between entities; there are some obvious inefficiencies with this, for example user_id is used in multiple entities, but they could all just have a relation with the user entity and take a user_id as a foreign key. Despite this problem, it would be a large hassle to revamp this, especially since there is pre-existing data already in place. So it will be outside our scope of improvements to the system unless time allows.



V3 Database Schema


Here is the relational schema of the new database, and from this we can see that the current database is in a much better spot. Firstly the tables have actual constraints and there is much less data duplication. This database currently has issues with storing files, so that is something to be worked on.
